Imbalance is a ratio of quoted limit order volumes between the bid and ask side.

$$I(t) = \frac{V_{bid}(t) - V_{ask}(t)}{V_{bid}(t) + V_{ask}(t)} \in [-1, 1]$$

Incorporating Price Change

Next, consider a two-dimensional CTMC $Z(t)$ that jointly models imbalance bin $\rho(t)$ and price change $\Delta S(t)$, where

$$\rho(t) \in \{1, 2, \dots, \#\text{bins}\}$$

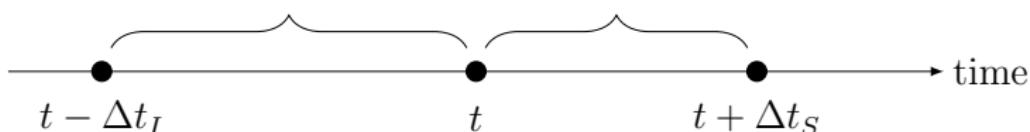

is the bin corresponding to imbalance averaged over the interval $[t - \Delta t_I, t]$, and

$$\Delta S(t) = \text{sgn}(S(t + \Delta t_S) - S(t)) \in \{-1, 0, 1\}$$

is the *sign* of the change in midprice of the *future* time interval Δt_S .

$\rho(t)$ is the imbalance bin of the time-weighted average of $I(t)$ over this past interval.

$\Delta S(t)$ is the sign of the midprice change over this future interval.

Transition Matrix

Arbitrage with
Order Imbalance

Anton D. Rubisov

Roadmap

Background
Information

Exploratory Data
Analysis

Maximizing Wealth
via Discrete-Time
Stochastic Control

Backtesting
Results

Conclusion and
Future Work

Using MLE, we obtain a generator matrix \mathbf{G} for the CTMC. The transition matrix over a step of size Δt_I is given by

$$\mathbf{P}(\Delta t_I) = [p_{ij}(\Delta t_I)] = e^{\mathbf{G}\Delta t_I}$$

called our *one-step transition probability matrix*. Matrix entries give the probability of transition from one (imbalance, price change) pair to another over the time interval Δt_I . This can be written semantically as

$$p_{ij} = \mathbb{P} [\varphi(\rho_{\text{curr}}, \Delta S_{\text{future}}) = j \mid \varphi(\rho_{\text{prev}}, \Delta S_{\text{curr}}) = i]$$

Predicting Future Price Change

Arbitrage with
Order Imbalance

Anton D. Rubisov

Roadmap

Background
Information

Exploratory Data
Analysis

Maximizing Wealth
via Discrete-Time
Stochastic Control

Backtesting
Results

Conclusion and
Future Work

Using Bayes' Rule, we can transform the P matrix to

$$\mathbb{P} \left[\Delta S_{\text{future}} = j \mid \begin{array}{l} \rho_{\text{curr}}=i \\ \rho_{\text{prev}}=k \\ \Delta S_{\text{curr}}=m \end{array} \right] = \frac{\mathbb{P} \left[\rho_{\text{curr}} = i, \Delta S_{\text{future}} = j \mid \begin{array}{l} \rho_{\text{prev}}=k \\ \Delta S_{\text{curr}}=m \end{array} \right]}{\mathbb{P} \left[\rho_{\text{curr}} = i \mid \begin{array}{l} \rho_{\text{prev}}=k \\ \Delta S_{\text{curr}}=m \end{array} \right]}$$

This allows us to predict future price moves. We'll call the collection of these probabilities the Q matrix.

Predicting Future Price Change

Sample \mathbf{Q} matrix.

	$\Delta S_{curr} < 0$			$\Delta S_{curr} = 0$			$\Delta S_{curr} > 0$

System Description

Impulse Control

$$\begin{pmatrix} x_k \\ s_k \\ z_k \\ q_k \end{pmatrix} = \begin{pmatrix} x_k \\ s_k \\ z_k \\ q_k \end{pmatrix} + \begin{pmatrix} s_k - \xi \\ 0 \\ 0 \\ -1 \end{pmatrix} M_k^- + \begin{pmatrix} -(s_k + \xi) \\ 0 \\ 0 \\ 1 \end{pmatrix} M_k^+$$

System Evolution

$$\begin{pmatrix} x_{k+1} \\ s_{k+1} \\ z_{k+1} \\ q_{k+1} \end{pmatrix} = \begin{pmatrix} x_k \\ s_k + \eta_{k+1, T(z_k, \omega_k)} \\ T(z_k, \omega_k) \\ q_k \end{pmatrix} + \begin{pmatrix} s_k + \xi + \delta_k^- \\ 0 \\ 0 \\ -1 \end{pmatrix} L_k^-$$

$$+ \begin{pmatrix} -(s_k - \xi - \delta_k^+) \\ 0 \\ 0 \\ 1 \end{pmatrix} L_k^+$$

Fill Probability

Arbitrage with
Order Imbalance

Anton D. Rubisov

Other agents' market orders are Poisson distributed, so

$$\mathbb{P}[K_k^+ = 0] = \frac{e^{-\mu^+(z)\Delta t} (\mu^+(z)\Delta t)^0}{0!} = e^{-\mu^+(z)\Delta t}$$

and

$$\mathbb{P}[K_k^+ > 0] = 1 - e^{-\mu^+(z)\Delta t}$$

- ▶ assume the *aggregate* of the orders walks the LOB to depth p_k
- ▶ if $p_k > \delta^-$, our sell limit order is lifted
- ▶ assume this occurs with probability $e^{-\kappa\delta^-}$.

$$\mathbb{E}[L_k^-] = (1 - e^{-\mu^+(z)\Delta t}) e^{-\kappa\delta^-} = \underbrace{p(\delta^-)}_{\text{short-hand}}$$

Dynamic Programming Value Function

Arbitrage with
Order Imbalance

Anton D. Rubisov

Our performance criterion is our *terminal wealth*:

$$V_k^{\delta^\pm}(x, s, z, q) = \mathbb{E}_{k,x,s,z,q} [W_T^{\delta^\pm}]$$
$$= \mathbb{E}_{k,x,s,z,q} \left[\underbrace{X_T^{\delta^\pm}}_{\text{cash}} + \underbrace{Q_T^{\delta^\pm} (S_T - \xi \operatorname{sgn}(Q_T^{\delta^\pm}))}_{\text{book value of assets}} - \underbrace{\alpha(Q_T^{\delta^\pm})^2}_{\text{penalty}} \right]$$

So that our dynamic programming equations are

$$V_T(x, s, z, q) = x + q(s - \xi \operatorname{sgn}(q)) - \alpha q^2$$

$$V_k(x, s, z, q) = \max_{\delta^\pm} \left\{ \sup \left\{ \mathbb{E}_{\mathbf{w}} [V_{k+1}(f((x, s, z, q), \mathbf{u}, \mathbf{w}_k))] \right\} ; \right.$$
$$V_k(x + s_k - \xi, s_k, z_k, q_k - 1) ;$$
$$\left. V_k(x - s_k - \xi, s_k, z_k, q_k + 1) \right\}$$

Optimal Posting Depth

Arbitrage with
Order Imbalance

Anton D. Rubisov

Solve one depth numerically (here the optimal sell depth):

$$\delta^{-*} = \max \left\{ 0 ; \frac{1}{\kappa} + \mathbb{E}[\eta_{0,T(z,\omega)}] - 2\xi \mathbb{1}_{q \geq 1} + \sum_j P_{z,j} \left[h_{k+1}(j, q) - h_{k+1}(j, q-1) \right] - (1 - e^{\mu^-(z)\Delta t}) e^{-\kappa \max \left\{ 0 ; \frac{1}{\kappa} - \mathbb{E}[\eta_{0,T(z,\omega)}] - 2\xi \mathbb{1}_{q \leq -1} + \sum_j P_{z,j} [h_{k+1}(j, q) - h_{k+1}(j, q+1)] \right.} \right. \\ \left. \left. - (1 - e^{\mu^+(z)\Delta t}) e^{-\kappa \delta^{-*}} (2\xi \mathbb{1}_{q=0} - \aleph(q)) \right\} (2\xi \mathbb{1}_{q=0} - \aleph(q)) \right\}$$

And substitute to solve for other depth:

$$\delta^{+*} = \max \left\{ 0 ; \frac{1}{\kappa} - \mathbb{E}[\eta_{0,T(z,\omega)}] - 2\xi \mathbb{1}_{q \leq -1} + \sum_j P_{z,j} [h_{k+1}(j, q) - h_{k+1}(j, q+1)] - p(\delta^-) \left(2\xi \mathbb{1}_{q=0} - \sum_j P_{z,j} [h_{k+1}(j, q-1) + h_{k+1}(j, q+1) - 2h_{k+1}(j, q)] \right) \right\}$$

Two Calibration Frameworks

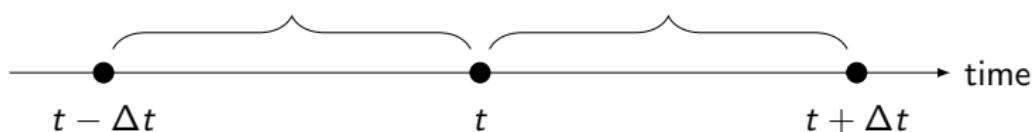

Arbitrage with
Order Imbalance

Anton D. Rubisov

Non- \mathcal{F} -predictable calibration

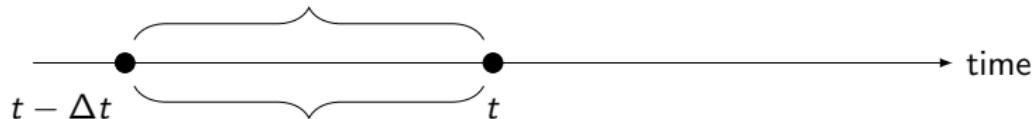

$\rho(t)$ is the imbalance bin of the time-weighted average of $I(t)$ over this past interval.

$\Delta S(t)$ is the sign of the midprice change over this future interval.

Regular calibration

$\rho(t)$ unchanged.

$\Delta S(t)$ calculated over the same past interval.

Backtesting
Results

Conclusion and
Future Work

- ▶ average return increases as the underlying stock liquidity increases;
- ▶ average return increases as the underlying stock bid-ask spread decreases;
- ▶ average return is stable and risk-adjusted return is improved when calibrating over a larger period of time, and is therefore preferred;
- ▶ there is no clear victor between regular calibration and the nFPC method.

Out-Of-Sample Backtesting: Annual Calibration

	Strategy	Average Return	Risk Adj Return	# MO	# LO	Average Invntry	% Win
INTC							
Continuous	—	0.209	2.112	2118	1758	0.44	98%
Discrete	—	0.372	1.591	949	1770	-5.89	98%
Continuous with nFPC	—	0.483	2.364	704	1693	1.46	100%

Discrete with nFPC	—	0.764	2.442	796	5559	3.85	100%

Out-Of-Sample Backtesting: Annual Calibration

Arbitrage with
Order Imbalance

Anton D. Rubisov

Back-of-the-envelope calculation:

Trade 100 shares at a time \times average strategy return
 \times average share price \times 249 (trading days)

**Trading INTC would have generated revenue of
\$384,705.**

**Trading AAPL would have generated revenue of
\$1,807,200.**

Capital requirements: 100 shares \times average share price
 \times 20 (maximum inventory) = \$250,000.

Return on investment (ROI) is 877%.

Conclusion and
Future Work

- ▶ Market order costs
- ▶ Discrete posting depths in increments of 1 tick
 - ▶ Can be solved by rounding...
- ▶ Our impact on the market (short-term price impact)
- ▶ Accounting for non-homogeneity
- ▶ Backtesting engine: information latency
- ▶ Backtesting engine: algorithm latency
- ▶ Backtesting engine: **tracking LOB queue position**
 - ▶ $e^{-\kappa\delta}$ fill probability is highly flawed

Thank you!

Dr. Gabriele D'Eleuterio

For acting as my supervisor and supporting me through the graduate school tumult.

Dr. Sebastian Jaimungal

For taking me on as a surrogate student and guiding me through the research.

Dr. Dmitri Rubisov (my dad)

For pretty much being a supervisor too.
